Definition 1 (Statistical Experiment)**.** *A* statistical experiment *is a triple* $(\mathcal{X}, \mathcal{F}, \{\mathbf{P}_\theta\}_{\theta\in\Theta})$ *where* $\mathcal{X}$ *is the sample space,* $\mathcal{F}$ *is a* σ*-algebra on* $\mathcal{X}$*, and* $\{\mathbf{P}_\theta\}$ *is a collection of of probability measures on* $\mathcal{X}$ *parametrized by* θ *in the parameter space* Θ*.*

Definition 2 (Sufficient Statistic)**.** *Let* $(\mathcal{X}, \mathcal{F}, \{\mathbf{P}_\theta\}_{\theta\in\Theta})$ *be an statistical experiment. Let a measurable function* $T : (\mathcal{X}, \mathcal{F}) \to (\mathcal{T}, \mathcal{G})$ *be a statistic. The statistic* T *is said to be* sufficient *if* $\mathbf{P}_\theta(\cdot \,|\, T)$ *does not depend on* θ*.*

Example 1. *Consider an experiment* $(\mathcal{X}, \mathcal{F}, \{\mathbf{P}_\theta\}_{\theta\in[0,1]})$ *where* $\mathcal{X} = \{0, 1\}^n$*,* $\mathcal{F}$ *is the power set of* $\mathcal{X}$*, and* $\mathbf{P}_\theta$ *is the joint distribution of* n *iid Bernoulli*(θ) *distributions. Define statistic* $T(x) \coloneqq \sum_{i=1}^n x_i$ *where* x_i *denotes the* i*-th component of* x*. We check that* T *is a sufficient statistic: Given any* $x \in \mathcal{X}$*, let* $t \coloneqq T(x)$ *and we have*

$$\mathbf{P}_\theta\{X = x \,|\, T = t\} = \frac{\mathbf{P}_\theta\{X = x\}}{\mathbf{P}_\theta\{T = t\}} = \frac{\prod_{i=1}^n \theta^{x_i}(1-\theta)^{1-x_i}}{\binom{n}{t}\theta^t(1-\theta)^{n-t}} = \binom{n}{t}^{-1}.$$

Since the conditional distribution does not depend on θ*,* T *is a sufficient statistic.*

Theorem 1 (Fisher-Neyman Factorization)**.** *Consider a statistical experiment* $(\mathcal{X}, \mathcal{F}, \{\mathbf{P}_\theta\}_{\theta\in\Theta})$*. A statistic* $T : (\mathcal{X}, \mathcal{F}) \to (\mathcal{T}, \mathcal{G})$ *is a sufficient statistic iff there exists measurable functions* $\{g_\theta\}_{\theta\in\Theta}$ *defined on* $(\mathcal{T}, \mathcal{G})$ *and* h *defined on* $(\mathcal{X}, \mathcal{F})$ *such that the probability density function can be decomposed as*

$$f(x \,|\, \theta) = g_\theta(T(x))h(x). \tag{1}$$

Proof. We only show the proof for discrete random variables. [1] In this case, we have the probability density function $f(x \,|\, \theta) = \mathbf{P}_\theta\{X = x\}$.

($\Rightarrow$) Suppose that T is sufficient. Given any realization $x \in \mathcal{X}$, let $t \coloneqq T(x)$ and we have the following

$$\begin{aligned}\mathbf{P}_\theta\{X = x\} &= \mathbf{P}_\theta\{X = x, T = t\} \\ &= \mathbf{P}_\theta\{X = x \,|\, T = t\}\,\mathbf{P}_\theta\{T = t\} \\ &= \underbrace{\mathbf{P}\{X = x \,|\, T = t\}}_{h(x)}\underbrace{\mathbf{P}_\theta\{T = t\}}_{g_\theta(t)}\end{aligned}$$

where the last equality is obtained by the definition of sufficiency.

($\Leftarrow$) Suppose we have the factorization (1). Given any realization $x \in \mathcal{X}$, let $t \coloneqq T(x)$ and we have

$$\begin{aligned}\mathbf{P}_\theta\{X = x \,|\, T = t\} &= \frac{\mathbf{P}_\theta\{X = x, T = t\}}{\mathbf{P}_\theta\{T = t\}} \\ &= \frac{g_\theta(t)h(x)}{\mathbf{P}_\theta\{T = t\}}\end{aligned}$$

[1] For continuous random variables, one must deal with measure-theoretic technicalities in the proof. One can find a proof for general random variables in *Chapter 2.2 Statistics and Sufficiency* from [1].

where the second equality is obtained by using the factorization on the numerator. Now consider the denominator, we have

$$\mathbf{P}_\theta\{T = t\} = \sum_{x':T(x')=t} \mathbf{P}_\theta\{X = x'\} = \sum_{x':T(x')=t} g_\theta(t)h(x')$$

where the second equality is obtained by factorization. Substitute the result back and we have

$$\begin{aligned}\mathbf{P}_\theta\{X = x \,|\, T = t\} &= \frac{g_\theta(t)h(x)}{\sum_{x':T(x')=t} g_\theta(t)h(x')} \\ &= \frac{h(x)}{\sum_{x':T(x')=t} h(x')}\end{aligned}$$

where the final expression does not depend on θ. Hence T is a sufficient statistic for θ. #

Example 2 (Example 1 Continued)**.** *Now we check that $T(x) = \sum_{i=1}^n x_i$ is a sufficient statistic using Theorem 1:*

$$\mathbf{P}_\theta\{X = x\} = \prod_{i=1}^n \theta^{x_i}(1-\theta)^{1-x_i} = \underbrace{\theta^{T(x)}(1-\theta)^{n-T(x)}}_{g_\theta(T(x))}.$$

In this case, $h(x) = 1$ is a constant function. Hence, T is a sufficient statistic.

Definition 3 (Sufficiency Principle)**.** *Let $(\mathcal{X}, \mathcal{F}, \{\mathbf{P}_\theta\}_{\theta\in\Theta})$ be a statistical experiment and let T be a sufficient statistic. The* sufficiency principle *states that inference about θ should depend only on T. That is, if two samples x and x' satisfies $T(x) = T(x')$, then they should lead to the same inference about θ.*

Remark 1. *The concept of sufficient statistic and the sufficiency principle are both due to Sir Ronald Fisher in the early 20th century.*
